

## PREN NUMBER

*A look at how pitting resistance equivalent numbers (PREN) are determined and what they do -- and do not -- tell you about a material*

Pitting corrosion resistance is an essential attribute to consider when choosing components and materials for a piping system.

However, resistance levels change based on metallurgic composition and with the sheer variety of options available today, having a clear idea of corrosion resistance just by name or grade is nearly impossible.

This is where pitting resistance equivalent numbers (PRENs) — also known as pitting resistance equivalent values (PRE-values) can help.

While not absolute figures, PRENs offer a simple way to compare various alloys and their ability to withstand [pitting corrosion](#).

*“The PREN (or PRE) numbers are useful for ranking and comparing the different grades, but cannot be used to predict whether a particular grade will be suitable for a given application, where pitting corrosion may be a hazard.”*

While you should always consult an engineer to ensure your materials meet all requirements, we’re going to outline how PRENs are determined and what information this value provides.

## WHAT IS PITTING CORROSION?

Before you can understand what PREN values might tell you, it's important to know what they're related to — in this case pitting corrosion.

Pitting corrosion occurs on metals with protective films — such as stainless steel.

Often initiated by poor aeration or chemical exposure within the environment, this type of corrosion creates small localized attacks which spread quickly from the protective surface layer to the metal itself.

While sources of pitting corrosion may vary, common causes include exposure to:

- Bromides
- Chlorides
- Fluorides
- Hypochlorites
- Iodides
- Sulfides
- Water

## HOW IS THE PREN OF AN ALLOY DETERMINED?

Exact formulas might differ. For this guide, we'll be using two of the most widely accepted modelling formulas to determine resistance to localized pitting corrosion by chlorides.

These formulas determine the rating based upon levels of chromium (%Cr), molybdenum(%Mo), nitrogen(%N), and tungsten (%W) present in the alloy.

- $PREN = \%Cr + (3.3 \times \%Mo) + (16 \times \%N)$
- $PREN = \%Cr + 3.3 \times (\%Mo + 0.5\%W) + 16 \times \%N$

The first formula is commonly used for stainless and **duplex alloys** without tungsten while the second adjusts the model to account for the tungsten present in many super duplex stainless alloys.

## Common PREN Formulas

Without Tungsten

$$\%Cr + (3.3 \times \%Mo) + (16 \times \%N)$$

With Tungsten

$$\%Cr + 3.3 \times (\%Mo + 0.5\%W) + 16 \times \%N$$

**%Cr - Chromium**

**%Mo - Molybdenum**

**%N - Nitrogen**

**%W - Tungsten**

For either formula, results typically start around 16 and can reach numbers greater than 40. You can see an example of typical results using [data from the BSSA](#) below.

STEEL TYPE	CHROMIUM %	MOLYBDENUM %	NITROGEN %	PREN
<i>Ferritic Steels</i>				
430	16.0-18.0	NS	NS	16.0-18.0
